

Global CO₂ Emissions: Who Emits, How Much, and What's Chang

Fossil fuels & industry, 1750–2024

Data source: Global Carbon Budget 2025 via Our World in Data

Audience: Policy analysts, climate negotiators, sustainability researchers

Global CO₂ Emissions Grew from 6 Bt in 1950 to Over 35 Bt Today

Europe and the US Fell from 90% of Emissions in 1900 to Under 60%

China Now Emits More Than One-Quarter of Global CO₂

Per Capita Emissions Range from 0.1 t in Chad to ~14 t in the US

Inequality signal:

≈150× gap between lowest and highest

Lowest: Chad ~0.1 t

Highest large-country range: US/Canada

Per Capita Emissions Vary Widely: ~14 t in the US vs. ~9 t in China

Interpretation:

- China per capita remains below
- India remains low at ~2 t
- World avg ~4.5 t
- See figure_8.jpg (source brief) f

2024 Snapshot: Many Western Nations Cut Emissions While Part

Pattern in 2024:
Blue/negative: US, EU, UK declines
Red/positive: Russia, parts of SE Asia

Energy Mix Explains Why France and the UK Emit Far Less Per Capita

Comparative insight:

Among wealthy economies, emissions differ sharply because energy systems differ. Countries with larger nuclear and renewable electricity shares (e.g., France, UK, Portugal) tend to have lower per capita emissions than peers with higher fossil fuel dependence.

Policy implication: energy mix choices can materially decouple prosperity from CO₂ intensity.

Key Takeaways: Responsibility Is Shared but Unequal

Global emissions exceed 35 Bt per year and have not yet peaked.

China is the largest annual emitter, but per capita emissions remain below the US.

Historical responsibility is heavily concentrated in Europe and the US.

Per capita disparities remain extreme: roughly 150× between lowest and highest emitters.

Energy policy and technology choices can decouple living standards from emissions.
